At the heart of modern power electronics converters are power semiconductor switching devices. The emergence of wide bandgap (WBG) semiconductor devices, including silicon carbide and gallium nitride, promises power electronics converters with higher efficiency, smaller size, lighter weight, and lower cost than converters using the established siliconbased devices.

Trends in power semiconductor devices. Abstract: This paper reviews recent trends in power semiconductor device technology that are leading to improvements in power losses for power electronic systems. In the case of low voltage (<100 V) power rectifiers, the silicon P-i-N rectifier has been displaced by the silicon Schottky rectifier, and it is projected that the silicon TMBS rectifier will be the preferred choice in the future.

The power semiconductor consists of an integrated circuit (die) mounted on a substrate wafer. Traditionally, the substrate is a high purity silicon crystal that is specifically grown to exhibit desired properties, then sliced and polished into wafers. Additional layers are added using the epitaxy process.

The power amplifier device is a key component that boosts the RF power signals in base stations. It's based on two competitive technologies, silicon-based LDMOS or RF gallium nitride (GaN). GaN, a III-V technology, outperforms LDMOS, making it ideal for the high-frequency requirements for 5G. But GaN is expensive with some challenges in the fab.
