Upper motor neuron syndrome is the motor control changes that can occur in skeletal muscle after an upper motor neuron lesion. Following upper motor neuron lesions, affected muscles potentially have many features of altered performance including: weakness decreased motor control including decreased speed, accuracy and dexterity altered muscle tone – a decrease or increase in the

Upper motor neuron damage. The upper motor neuron extends from the cerebral cortex to the spinal cord. Damage to the upper motor neuron pathway results in a group of symptoms called the upper motor neuron syndrome. The initial damage to the cerebral cortex causes flaccidity of the muscles of the contralateral side to the damage.

Motor neurons that synapse above this level are called as UPPER MOTOR NEURONS and those that synapse at or below the level of the anterior horn cells are called LOWER MOTOR NEURONS. If an injury/lesion occur between the brain and the spinal cord i.e proximal to anterior horn, it will be called or considered as an UPPER MOTOR NEURON LESION.

The upper motor neuron (UMN) is the motor system that is confined to the central nervous system (CNS) and is responsible for the initiation of voluntary movement, the maintenance of muscle tone for support of the body against gravity, and the regulation of posture to provide a stable background upon which to initiate voluntary activity.

Upper motor neuron syndrome (UMNS) is common among TBI patients and often present bilaterally, unlike in stroke patients, in which unilateral dysfunction is more common. UMNS can significantly hinder a patient's ability to perform activities of daily living including their ability to transfer.

Amyotrophic lateral sclerosis (ALS), also called classical motor neuron disease, affects both the upper and lower motor neurons. It causes rapid loss of muscle control and eventual paralysis. Many doctors use the term motor neuron disease and ALS interchangeably.

The diagnosis of amyotrophic lateral sclerosis (ALS) requires recognition of both lower motor neuron (LMN) and upper motor neuron (UMN) dysfunction.<sup>1</sup> However, classical UMN signs are frequently difficult to identify in ALS.<sup>2</sup> LMN involvement is sensitively detected by electromyography (EMG),<sup>3</sup> but, as yet, there are no generally accepted markers for monitoring UMN abnormalities,<sup>4</sup> the ...

Injury of upper motor neurons is common because of the large amount of cortex occupied by the motor areas, and because motor pathways extend all the way from the cerebral cortex to the lower end of the spinal cord. The resulting changes in muscle performance that can be wide and varied are described overall as upper motor neuron syndrome

Motor neurone disease is an uncommon condition that mainly affects people in their 60s and 70s, but it can affect adults of all ages. It's caused by a problem with cells in the brain and nerves called motor neurones. These cells gradually stop working over time. It's not known why this happens.
